Thanks — these screenshots give me a much clearer view of the actual **SendFlow Coach** site. I can now assess the visible product experience rather than just the written specifications.

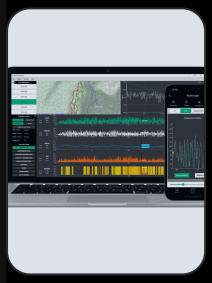

My first impression

The site already feels like a coherent product, not just a prototype made of disconnected screens. The dark interface, turquoise accents, yellow active states, telemetry overlays, and MTB-specific terminology give it a recognizable identity.

1. The visual identity is strong

The sidebar is consistent, the hierarchy is clear, and the colors distinguish navigation, actions, and analysis states. I would preserve this visual language rather than redesigning the site from scratch.

2. The analysis screen is the standout feature

The synchronized video, telemetry values, timeline, event markers, and categories such as *Vértice*, *Mira lejos*, and *Talones abajo* communicate what makes Coach different from a generic video-sharing platform. This is the part I would prioritize when refining the experience.

3. The workflow is easy to understand

Inicio → Enviar → Devoluciones → Mi plan → Mensajes → Bajadas creates a sensible journey from submitting a ride to receiving feedback and following a training plan.

What I would improve first

1. Make the coach–rider conversation more central

The screenshots show feedback, annotations, and messages, but the relationship between a particular descent, its analysis, and the discussion could be more explicit. Ideally, each submission should have one clear history: original upload, coach review, comments, rider questions, and revised feedback.

2. Clarify what each descent contains

Cards already distinguish video, Sender data, and data-only sessions. I would make those states more systematic and immediately scannable, including whether a coach has reviewed the submission and whether a response is pending.

3. Give “Mi plan” more useful context

The screen is clean, but mostly empty when there are few sessions. A plan summary, next session, progress through the current block, and completed-session history could make it feel useful between coaching sessions—without adding unnecessary features.

4. Verify the underlying behavior, not just the screens

These screenshots establish what the interface looks like; they don't prove that uploads resume correctly, videos and telemetry stay synchronized, permissions are enforced, or coach feedback persists reliably. Those remain important end-to-end tests.

A few details worth checking

- **Terminology:** “Enviar video o bajada” is understandable, but the upload flow should make the distinction between a video, a Sender descent, and both together unambiguous.
- **Status consistency:** “Con devolución,” “Aprobado,” and “Solo lectura” appear in different contexts. Define precisely what each means and use them consistently.
- **Analysis readability:** The telemetry panel is compelling, but on smaller screens the video, timeline, and annotation list will need careful responsive behavior.
- **Sample content:** The screenshots contain test-like titles and a “plan de prueba.” Fine for development, but production onboarding should make it obvious what is real data and what is an example.
- **Spanish copy:** The Argentine tone works well. I would keep it consistent throughout the product, including button labels, status messages, and error recovery.

How this changes my assessment of SendFlow

The screenshots make one thing particularly clear: **Coach is not merely an upload portal or a training-plan app. Its strongest identity is the connection between a rider’s actual descent, objective data, and actionable coaching feedback.** The training plan complements that loop.

My recommended priority remains to validate the complete journey with a real coach and rider, while separately validating the Sender hardware and real telemetry. The interface is already developed enough that the next major gains are likely to come from workflow clarity, reliability, and real-world validation—not from adding more screens.

One limitation: I can assess the visual design and the workflows suggested by these screenshots, but I can't establish whether the underlying controls and backend work correctly from screenshots alone.
