Make a “Beginner / Rider” mode that shows only actionable, simple insights and hides everything else by default.

Your current feature set is excellent for suspension tuners and experienced riders, but it is dense. The solution is not to remove capability — it is progressive disclosure + clear hierarchy + plain-language recommendations.

1. Core design principle

Create three explicit modes (user chooses once, can change later):

- **Rider / Beginner** (default for new users)
- **Intermediate**
- **Tuner / Expert** (everything you have today)

Most people will stay in Rider mode forever. Only show the full power when they ask for it.

2. What a Beginner should see (and what to hide)

Always visible / primary screens for noobs:

Priority	What to show	How to present it	Why it matters
1	**Setup Health**	Traffic-light cards (green/yellow/red) + 1 - sentence recommendation	“Your SAG is good”, “You’re bottoming out too much in the rear”, “Rebound is too slow in the front”
2	**Ride Summary**	Big numbers + short comments	Total time, max speed, number of jumps, number of hard hits, average speed
3	**Bottom-outs & Big Hits**	Count + map markers + simple advice	“You bottomed 4 times. Try +1 token or higher pressure”
4	**Front / Rear Balance**	Simple bar or percentage + “balanced / front-heavy / rear-heavy”	Riders feel this immediately
5	**SAG (static + dynamic)**	Current vs target + “good / a bit soft / a bit stiff”	Most important single number for most people
6	**One recommended change**	Single clear suggestion	“Increase rear spring by 1 token” or “Slow rebound 1 click front”

Hide by default (or put behind “Show more / Expert”):

- Velocity zones (HSR/LSR/LSC/HSC) and symmetry index
- Histograms / distributions
- g-g diagram
- Raw compression/rebound averages and peaks
- Travel budget details
- Dynamic head angle
- Full event tables
- Pressure curves, fade detection, spring tokens suggestions (unless they trigger a recommendation)
- Terrain classification details
- TMD vibration spectra
- Everything in Taller / maintenance history (except a simple “service due” warning)

3. Concrete UX patterns that work well

A. Traffic-light dashboard (you already have the seeds of this)
Keep your “Semáforos” idea but make it the hero of the home screen:

- SAG
- Bottom-outs
- Rebound balance
- Overall “ride quality” score (you can invent a simple composite)

Each light has a short plain-language explanation and a “Why?” expandable that shows the underlying numbers only if they want.

B. “What should I change?” card
After every ride (or after a few rides), show one primary recommendation in big text:

> *“Your rear is packing and bottoming. Try +1 token on the spring or +5 psi.”*

Secondary suggestions can be smaller or behind a “More ideas” button.

C. Guided first-time experience
When someone opens the app the first time:

1. Ask weight, riding style (aggressive / smooth), and skill level.

2. Help them set static SAG with live feedback (you already have this).
3. After the first ride, walk them through the 4–5 most important cards only.

D. Progressive disclosure everywhere

- Default view = simple cards + map with only jumps, bottoms and markers.
- “Advanced” toggle or long-press to reveal histograms, velocity zones, full event list, etc.
- Tabs can stay, but rename or reorder them for beginners: Summary → Events → Map → Setup → More.

E. Language
Replace technical terms with rider language where possible:

- “Bottom-out” instead of “tope D/T/DT”
- “Packing” → “The suspension is staying compressed”
- “High-speed rebound” → “How fast it returns after big hits”
- Keep the technical terms available under a small “i” or “Details”.

4. Suggested information hierarchy for Rider mode

Home / After-ride screen

1. Big traffic lights (SAG, bottoms, balance, rebound)
2. One clear recommendation
3. Ride stats (time, max speed, jumps, hard hits)
4. Map with only the important events highlighted
5. “Compare with last ride” (simple gain/loss)

Secondary (still accessible but not primary)

- Jump details (air time, landing G)
- Braking events (only if they are extreme)
- Simple front/rear travel used

Never primary for beginners

- Raw mm/s numbers
- Multiple velocity zone percentages

- Full movement table
- Pressure curves / temperature / fade (unless it triggers a warning)

5. Extra ideas that reduce overwhelm

- **“Focus mode”**: After a ride the user can choose “I only care about bottoms today” or “I only care about balance” and the app filters everything else.
- **Session vs season view**: Beginners care more about “this run” and “this weekend” than deep historical analysis.
- **Export / share simplified PDF**: A one-page “Ride report for my mechanic” that only contains the traffic lights + recommendation + key events. Keep the full expert PDF for when they want it.
- **Optional coaching tips**: Small contextual tips (“You spent a lot of time in the last 20 % of travel — that usually means the spring is too soft or the damping is too slow”).

Summary recommendation

Keep 100 % of the current analytical power for the Expert mode.

Create a clean **Rider mode** that surfaces only:

- Traffic lights for the 4–5 things that matter most
- One clear next action
- Basic ride stats + map of important events
- Static + dynamic SAG

Everything else stays one tap or one mode switch away. That way the app stays powerful for you and for tuners, but feels simple and useful for normal riders from day one.

If you want, I can sketch the exact card layout / hierarchy for the Rider home screen or help rewrite the key labels into plain rider language.
